This paper looks at a type of ocean animal that doesn't breathe oxygen like many animals do. This ocean animal usually lives where there are lots of waves. It can live in parts of the ocean that don't have much air to breathe. The scientists looked for stuff that other animals have inside them to breathe, but could not find them in this animal. It looks like this animal might use the stuff its body/shell is made up of to help it breathe. We can use this animal to learn more about ocean-breathing when there is not much air to breathe.
